  - Steven E. Rigdon, PhD
- Committee Members:
  - Fadel Megahed, PhD (Farmer School of Business, Miami University)
  - Hong Xian, PhD
- At-large Committee:
  - Kenton Johnson, PhD
  - Juliet Iwelunmor, PhD

# 1 The problem

# Transportation and trucks

**Transportation safety** deserves attention:

- The 8-th leading cause of death globally in 2016,<sup>1</sup>
- 1.4 million people were killed, mostly aged 4 to 44 years old,<sup>1</sup>
- a loss of 518 billion dollars.<sup>2</sup>

**Trucks** are the backbone of the economy:

- 70% of freights were delivered by trucks,
- 71.3% of domestic goods and 73.1% of value,<sup>3,4</sup>

# Challenges for trucking industry

## Drivers:

1. drive alone for long hours,
2. work under time demands, challenging weather and traffic conditions,
3. sleep deprivation and disorders

## Trucks:

1. huge weights,
2. large physical dimensions,
3. potentially carry hazardous cargoes.

## Truck crash studies

Traditional studies almost exclusively use data that ultimately trace back to **post hoc vehicle inspection, interviews** with survived drivers and witnesses, and **police reports**.<sup>5,6</sup>

1. rare events → difficulty in estimation,<sup>7</sup>
2. retrospective studies → recall bias,<sup>8</sup>
3. crashes are under-reported → selection bias.<sup>9,10</sup>

## Naturalistic driving studies (NDS)

**NDS** uses

*unobtrusive devices, sensors, and cameras installed on vehicles to proactively collect frequent naturalistic driving behavior and performance data under real-world driving conditions<sup>5,11</sup>*

1. driver-based data, not road segment-based,
2. high-resolution driver behavior and performance data,
3. less costly and difficult per observation.

## Safety Critical Events (SCEs)

**SCEs** are

*a chain of adverse events following an initial off-nominal event, which can result in an accident if compounded with additional adverse conditions.<sup>12</sup>*

Examples of SCEs are:

1. hard brakes,
2. headways,
3. rolling stability,
4. collision mitigation

## The problem

NDSs are relatively *new* and *less studied*. Here are **several problems** in NDS.

1. Are SCEs indicative of **real crashes** among truck drivers?
2. Can we **predict** SCEs?
3. How can we **innovate existing models** to account for features of NDS?

## 2 Literature review

# Association between crashes and SCEs

Examples of studies supporting SCEs:

- hard braking events were significantly associated with collisions and near-crashes,<sup>13</sup>
- a significant positive association between crashes, near crashes, and crash-relevant incidents,<sup>14</sup>
- ...

Examples of studies that are against SCEs:

- overspeed negatively associated with injury crashes,<sup>15</sup>
- no harm, no validity,<sup>16</sup>
- no demonstration on causal link between SCEs and injury crashes.<sup>17</sup>

Gaps:

- Limited number of drivers → less convincing (< 100),
- No studies specifically on truck drivers.

# Fatigue

The **most important factor** in transportation safety studies. Fatigue is

*a multidimensional process that leads to diminished worker performance, which may be a result of prolonged work, psychological, socioeconomic, and environment factors*

- 16.5% of fatal traffic accidents,<sup>18</sup>
- 12.5% of injuries-related collisions,<sup>18</sup>,
- 60% of fatal truck crashes.<sup>19</sup>

However, fatigue is hard to measure in transportation safety studies.

- ocular and physiological metrics,
- sleep patterns,
- **cumulative driving time.**

## Other risk factors

Four aspects of risk factors are included in previous studies:

- Driver characteristics,
- Weather
- Traffic
- Road features
- ...

Gaps in literature:

1. Lack of **high-resolution** weather and traffic data,
2. No fusion of NDS and **API data**.

# Statistical models

- Logistic regression,
- Poisson regression,
- machine learning models,
- ...

Gaps in literature:

1. Road-centric models, not driver-centric models,
2. Maximum likelihood estimation (MLE) limited in rare-event models,
3. Lack of recurrent events models.

## Bayesian models

In the Bayesian perspective, parameters are viewed as **random variables** that have probability distributions:<sup>20</sup>

$$\begin{aligned} p(\theta|\mathbf{X}) &= \frac{p(\theta)p(\mathbf{X}|\theta)}{p(\mathbf{X})} \\ &= \frac{p(\theta)p(\mathbf{X}|\theta)}{\int p(\theta)p(\mathbf{X}|\theta)d\theta} \end{aligned} \tag{1}$$

- $p(\theta)$ : subjective priors,
- $p(\mathbf{X}|\theta)$ : the likelihood function,
- $p(\mathbf{X}) = \int p(\theta)p(\mathbf{X}|\theta)d\theta$ : the normalizing constant, **trickiest** part,
- $p(\theta|\mathbf{X})$ : the posterior distribution.

The posterior distribution is a balance between the **prior beliefs** and the **likelihood function**.

# Challenges for Bayesian models in a big data setting

Modern Bayesian inferences relies on **Markov chain Monte Carlo (MCMC)** to overcome the intractable denominator issue. However, MCMC is not scalable in the big data setting:

- **Tall data** (a lot of observations),
- **Wide data** (a lot of variables),
- **Correlation between variables** (hierarchical models).<sup>21</sup>

Potential solutions:

- [Hamiltonian Monte Carlo](#),<sup>22</sup>
- [Subsampling MCMC](#) such as Energy Conserving Subsampling Hamiltonian Monte Carlo (ECS-HMC).<sup>23</sup>

# Conceptual framework

1. *Truck Driver Fatigue Model*,<sup>24</sup>
2. *5× ST-level hierarchy theory in traffic safety*,<sup>25</sup>
3. *Commercial motor vehicle driver fatigue framework*.<sup>6</sup>

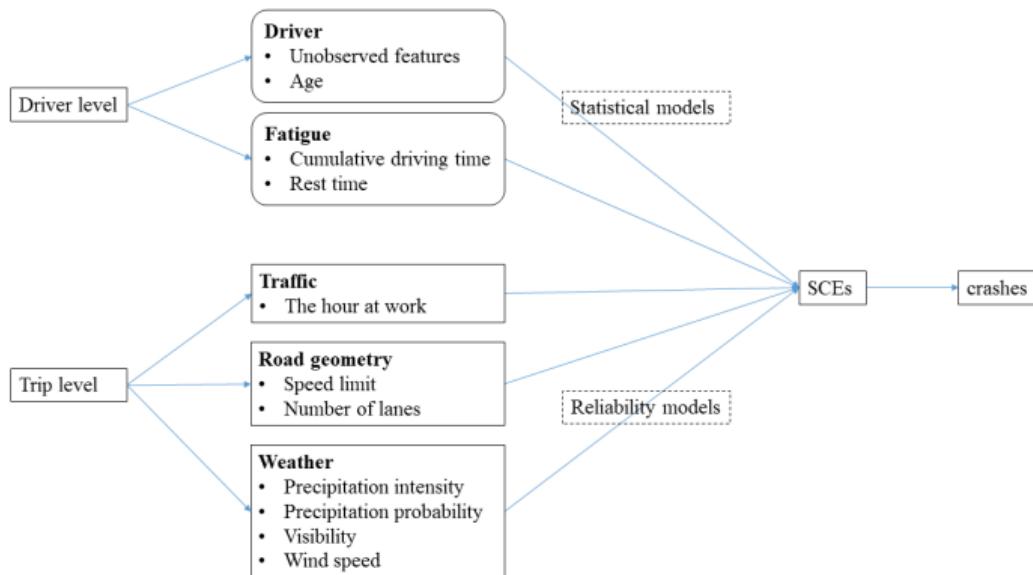

Figure 1: Conceptual model. SCEs represent safety critical events.

### 3 Research aims

## Overall aim

Gaps in previous literature:

1. The association between **crashes and SCEs** has not been confirmed among truck drivers,
2. Difficulty in **fusing high-resolution NDS and API data**,
3. Bayesian inference is not **scalable** in tall and wide NDS data setting,
4. **Recurrent events models** were not widely applied in NDS data.

The overarching goal of this proposed dissertation is to construct **scalable Bayesian hierarchical models** for NDS data and understand how **cumulative driving time** and other environmental factors will impact the performance of truck drivers.

## Aim 1

*To examine the association between truck crashes and SCEs using a Bayesian Gamma-Poisson regression.*

I hypothesize that the rate of crashes is positively associated with the rate of SCEs among the truck drivers controlling for the miles driven and other covariates.

## Aim 2

*To construct three scalable Bayesian hierarchical models to identify potential risk factors for SCEs.*

I hypothesize that the patterns of SCEs vary significantly from drivers to drivers and can be predicted using cumulative driving time, weather, road geometry, driver's age, and other factors.

- 2a) Bayesian hierarchical **logistic** regression,
- 2b) Bayesian hierarchical **Poisson** regression,
- 2c) Bayesian hierarchical **non-homogeneous Poisson process (NHPP)** with the power law process (PLP) intensity function.

## Aim 3

*To propose an innovative reliability model that accounts for both within shift cumulative driving time and between-trip rest time.*

I hypothesize that **between-trip rest time** can **recover** the intensity function by **some proportion  $\kappa$** , and intensity function varies significantly from drivers to drivers.

## 4 Data

## Data sources

1. **Real-time ping:** vehicle number, date and time, latitude, longitude, driver identification number (ID), and speed at that second (every 2-10 minutes), ~1.4 billion pings (150 GB .csv file),
2. **Truck crashes and SCEs:** hard brakes, headways, and rolling stability were collected if kinematic thresholds were met,
3. **Driver demographics:** age,
4. **Weather from the DarkSky API** (500 drivers): precipitation intensity, precipitation probability, wind speed, and visibility,
5. **Road geometry from the OpenStreetMap** (500 drivers): speed limits and the number of lanes.

## Demonstration of data I

farj7	30.35165	-91.68755	60	2

## Geographical distribution of active moving pings

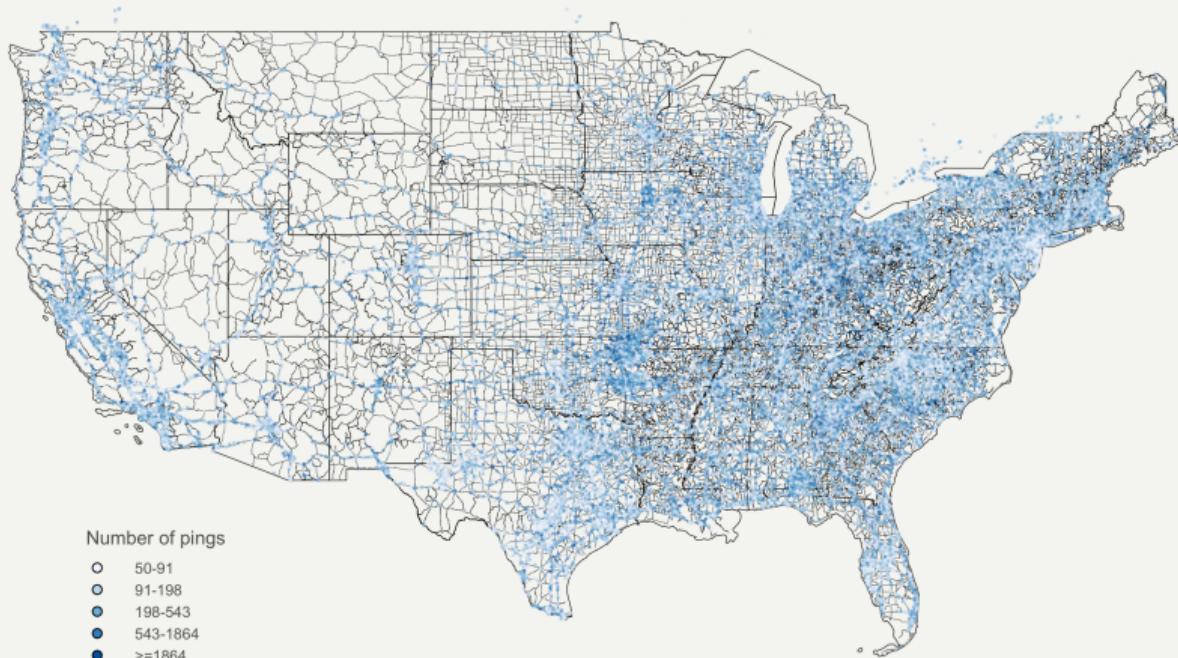

A large commercial truck NDS data set in USA, 2015-2016

The grey line are major highways in the USA. Only locations with at least 50 pings were shown.

## Geographical distribution of stopped pings

A large commercial truck NDS data set in USA, 2015-2016

The grey lines are major highways in the USA. Only locations with at least 50 pings were shown.

## Data aggregation

1. **Shift:** the trips data will be further divided into different shifts if the specific driver was [not moving for eight hours](#),
2. **Trip:** for each of the truck drivers, if the real-time ping data showed that the truck was [not moving for more than 30 minutes](#), the ping data will be separated into two different trips (~200,000 rows),
3. **30-minute intervals:** as the length of a trip can vary significantly from 5 minutes to more than 8 hours, I will transform the trips data into [standardized 30-minute fixed intervals](#) according to the starting and ending time of trips (~1 million rows).

## 5 Methods

## Aim 1 - Data and variables

*The first aim seeks to determine the association between the rate of crashes and the rate of SCEs at the level of drivers.*

- **Data:**
  - over 50,000 commercial truck drivers,
  - 1,494,678,173 pings,
  - 35,008 crashes, 480,331 SCEs
- **outcome variable:** the number of crashes for each driver.
- **The primary independent variable:** the number of SCEs per 10,000 miles. These SCEs will be further decomposed into the number of hard brakes, headways, and rolling stability per 10,000 miles in similar analysis.
- **The covariates:** the total miles driven, the percent of night driving, and the age of the drivers.

## Aim 1 - Gamma-Poisson model

Here is how the proposed Gamma-Poisson model will be implemented. Let us assume that:

$$\begin{aligned}\lambda &\sim \text{Gamma}(\alpha, \beta) \\ X|\lambda &\sim \text{Poisson}(\lambda)\end{aligned}$$

Then we have:

$$X \sim \text{Gamma-Poisson}(\alpha, \beta)$$

The Gamma-Poisson distribution is a  $\alpha$ -parameter distribution. The log-linear Gamma-Poisson model will be specified as:

$$\log \beta = \mathbf{X}\gamma - \log m,$$

- $\mathbf{X}$  is the predictor variables matrix, including age, gender, mean speed, business unit, and driver types,
- $\gamma$  is the associated  $2 * 1$  parameter vector,
- $m$ : is the total miles driven as an offset term,
- $\alpha$ : a fixed overdispersion parameter.

## Aim 1 - potential problems and alternative plans

*The sheer size of the original ping data may be a problem in aim 1: the ping data has 1,494,678,173 rows and 9 columns, (>140 gigabytes (GB) . csv).*

Although I will use the OSC server that has Random-Access Memory (RAM) of more than 500 GB, it may still be hard to read and process this giant file.

1. If the OSC server cannot handle the data correctly, I will separate the single giant csv file into **several small csv files** according to driver ID, then aggregate the pings to trips for each small csv file.
2. After the ping data are aggregated to trips, it is unlikely that the log-linear Gamma-Poisson model fail. In that unlikely event, I can turn to **negative binomial models** or use **traditional MLE estimates** instead of Bayesian estimation.

## Aim 2 Overview

*The purpose of aim 2 is to develop three **scalable hierarchical Bayesian statistical and reliability models** for the SCEs of truck drivers and identify potential risk factors.*

- **Data:** 30-minute intervals for 496 drivers,
- **Outcome:**
  - whether SCEs occurred or not (binary variable),
  - the number of SCEs (count variable),
  - the time to each SCE (in minutes),
- **Predictors:**
  - driver-level random-effects,
  - age,
  - cumulative driving time,
  - weather,
  - road geometry,
  - mean speed,
  - speed variation,

## Aim 2a) Bayesian hierarchical logistic regression

Two-level model: 1) 30-minute interval level  $i$ , 2) driver level  $d(i)$ .

$$Y_i \sim \text{Bernoulli}(p_i)$$

$$\log \frac{p_i}{1 - p_i} = \beta_{0,d(i)} + \beta_{1,d(i)} \cdot CT_i + \sum_{j=1}^J x_{ij} \beta_j \quad (2)$$

$$\beta_{0,d} \sim \text{i.i.d. } N(\mu_0, \sigma_0^2), \quad d = 1, 2, \dots, D$$

$$\beta_{1,d} \sim \text{i.i.d. } N(\mu_1, \sigma_1^2), \quad d = 1, 2, \dots, D$$

- $Y_i$ : whether SCEs occurred in the 30-minute interval or not (binary),
- $\beta_{0,d(i)}$ : random intercepts for each driver,  $\beta_{1,d(i)}$  is random slopes for cumulative driving time  $CT_i$ ,
- $\beta_2, \beta_3, \dots, \beta_J$ : fixed parameters for covariates  $x_{ij}$ .
- $\mu_0, \sigma_0$ : hyper-parameters for random intercepts  $\beta_{0,d}$ ,
- $\mu_1, \sigma_1$ : hyper-parameters for random slopes  $\beta_{1,d}$ .

## Aim 2a) Priors

Since we do not have much prior knowledge on the parameters, I will assign weakly informative priors<sup>26</sup> for these parameters:

$$\begin{aligned}\mu_0 &\sim N(0, 5^2) \\ \mu_1 &\sim N(0, 5^2) \\ \sigma_0 &\sim \text{Gamma}(1, 1) \\ \sigma_1 &\sim \text{Gamma}(1, 1) \\ \beta_2, \beta_3, \dots, \beta_J &\sim N(0, 10^2)\end{aligned}\tag{3}$$

The priors for the hyperpriors need to be relatively more restrictive than priors for fixed-effects parameters  $\beta_2, \beta_3, \dots, \beta_J^{20}$ .

## Aim 2b) Model 2: Bayesian hierarchical Poisson regression

Two-level model: 1) 30-minute interval level  $i$ , 2) driver level  $d(i)$ .

$$N_i \sim \text{Poisson}(T_i \cdot \lambda_i)$$

$$\log \lambda_i = \beta_{0,d(i)} + \beta_{1,d(i)} \cdot \text{CT}_i + \sum_{j=1}^J x_{ij} \beta_j \quad (4)$$

$$\beta_{0,d} \sim \text{i.i.d. } N(\mu_0, \sigma_0^2), \quad d = 1, 2, \dots, D$$

$$\beta_{1,d} \sim \text{i.i.d. } N(\mu_1, \sigma_1^2), \quad d = 1, 2, \dots, D$$

- $Y_i$ : the number of SCEs occurred in the 30-minute interval,
- $T_i$ : length of the 30-minute interval,
- The other components are the same as those in hierarchical logistic regression.

The scalable Bayesian statistical and reliability models will be conducted using the **HMC-ECS algorithm** (self-defined functions in Python 3.6.0) or **HMC** (the `rstan` package in statistical computing environment R 3.6.0)<sup>23,27,28</sup>.

## Aim 2c) motivation for recurrent event models

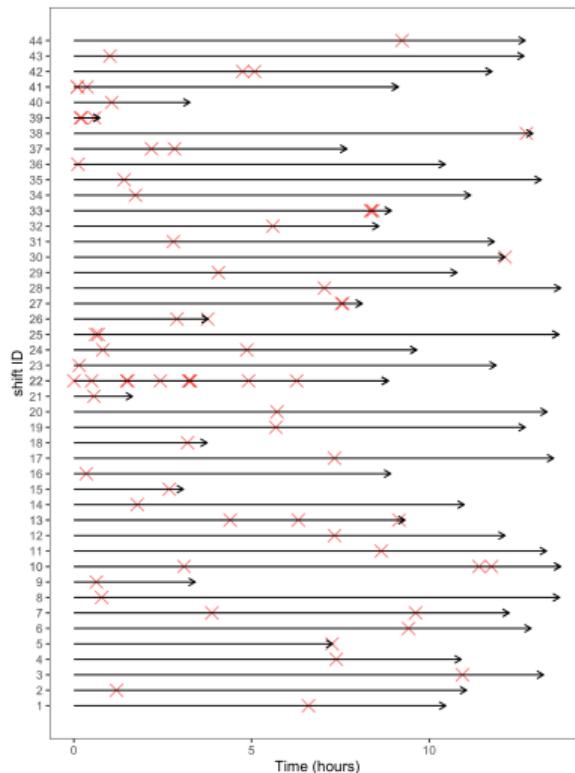

Figure 2: An arrow plot of time to SCEs in each shift

## Aim 2c) Theories on NHPP and PLP

### Nonhomogeneous Poisson Process (NHPP):

*a Poisson process whose intensity function is non-constant.*

**Power law process (PLP):** a NHPP with the intensity function of:

$$\lambda(t) = \frac{\beta}{\theta} \left( \frac{t}{\theta} \right)^{\beta-1}, \quad \beta > 0, \theta > 0 \quad (5)$$

- $\beta > 1$ : intensity increasing → reliability deteriorating,
- $\beta = 1$ : constant intensity → reliability not changing,
- $\beta < 1$ : intensity decreasing → reliability improving,
- $\theta$ : scale parameter.

There are two forms of truncation in a NHPP:

1. *Failure truncation:* when testing stops after a predetermined number of failures,
2. *Time truncation:* when testing stops at a predetermined time  $t$ .

## Aim 2c) Intensity function of NHPP

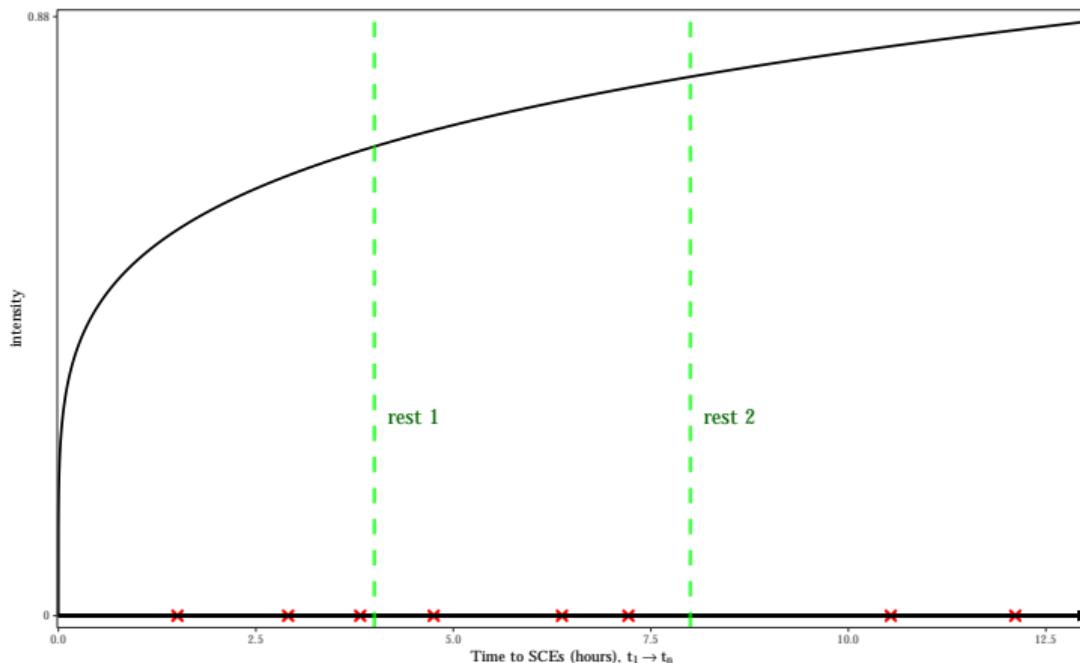

Figure 3: Intensity function, time to SCEs, and rest time within a shift generated from a NHPP with a PLP intensity function,  $\beta = 1.2, \theta = 2$

## Aim 2c) Notations

Let  $T_{d,s,i}$  denotes the time to the  $d$ -th driver's  $s$ -th shift's  $i$ -th critical event. The total number critical events of  $d$ -th driver's  $s$ -th shift is  $n_{d,s}$ . The ranges of these notations are:

- $i = 1, 2, \dots, n_{d,S_d}$ : SCE ID,
- $s = 1, 2, \dots, S_d$ : shift ID,
- $d = 1, 2, \dots, D$ : driver ID.

## Aim 2c) Bayesian hierarchical NHPP with PLP intensity function

Assume the time to SCEs within the  $d$ -th driver's  $s$ -th shift were generated from a PLP, with a fixed shape parameter  $\beta$  and varying scale parameters  $\theta_{d,s}$  across drivers  $d$  and shifts  $s$ .

$$\begin{aligned} T_{d,s,1}, T_{d,s,2}, \dots, T_{d,s,n_{d,s}} &\sim \text{PLP}(\beta, \theta_{d,s}) \\ \beta &\sim \text{Gamma}(1, 1) \\ \log \theta_{d,s} &= \gamma_{0d} + \gamma_1 x_{d,s,1} + \gamma_2 x_{d,s,2} + \dots + \gamma_k x_{d,s,k} \\ \gamma_{01}, \gamma_{02}, \dots, \gamma_{0D} &\sim \text{i.i.d. } N(\mu_0, \sigma_0^2) \\ \gamma_1, \gamma_2, \dots, \gamma_k &\sim \text{i.i.d. } N(0, 10^2) \\ \mu_0 &\sim N(0, 10^2) \\ \sigma_0 &\sim \text{Gamma}(1, 1) \end{aligned} \tag{6}$$

The shape parameter  $\beta$  shows the reliability changes of drivers:

- $\beta > 1$ : intensity increasing → reliability deteriorating,
- $\beta = 1$ : constant intensity → reliability not changing,
- $\beta < 1$ : intensity decreasing → reliability improving,

## Aim 2c) Potential problems and alternative plans

*The sheer size of the 30-minute interval table and merged shifts table may be a problem in this aim.*

- The 30-minute interval table: ~one million rows and 10 variables,
- Merged shift table: ~200,000 rows and 10 variables.
- 496 random intercepts and slopes

Although I propose to use the HMC-ECS to estimate the random effect, there are still chances that the model does not work. In that case, I will **sample 50 to 200 typical drivers**, then conduct the analysis based on this smaller sample data. In the unlikely event that the models still fails based on this smaller data, I can restrict the hierarchical models to **random intercepts only model** or use **traditional MLE** instead of Bayesian estimation.

## Aim 3

*Aim 3 seeks to innovate the NHPP with a PLP intensity function proposed in Aim 2 by adding one more parameter  $\kappa$ .*

I propose to account for the rest time within a shift by adding one **more parameter  $\kappa$ , the percent of reliability recovery** for each a break within a shift.

This new reliability model (**jump-point PLP (JPLP)**) will be between a NHPP where the intensity function is not influenced by between-trip rests ("as bad as old"), and a *renewal process* where the intensity function is fully recovered by between-trip rests ("as good as new").

## Aim 3 - intensity function of NHPP

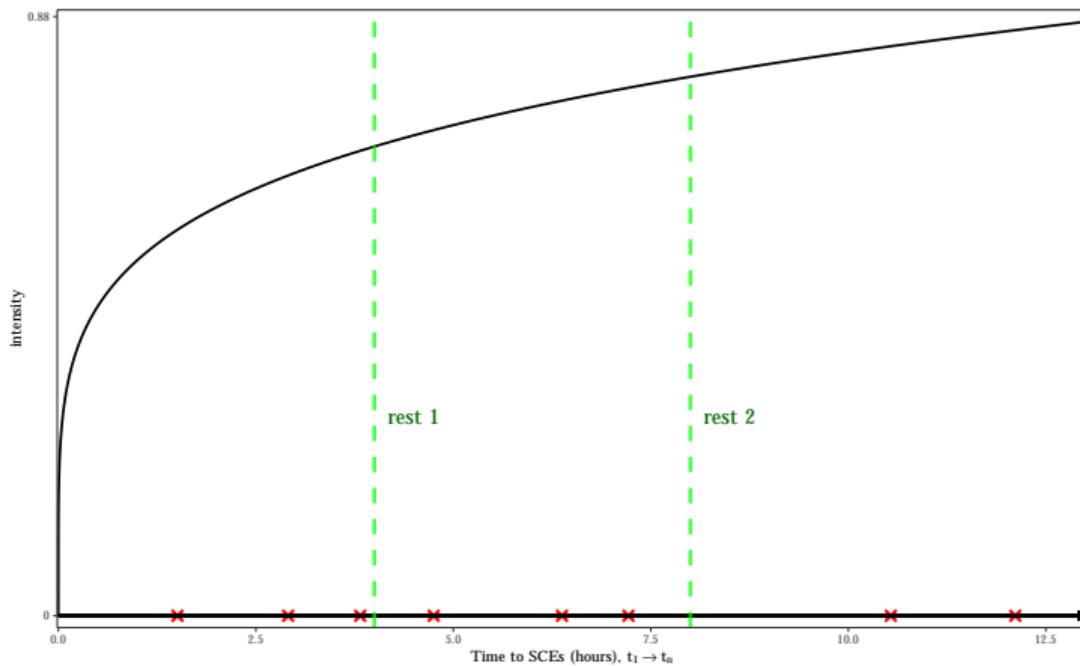

Figure 4: Intensity function, time to SCEs, and rest time within a shift generated from a NHPP with a PLP intensity function,  $\beta = 1.2, \theta = 2$

## Aim 3 - intensity function of proposed jump-point PLP (JPLP)

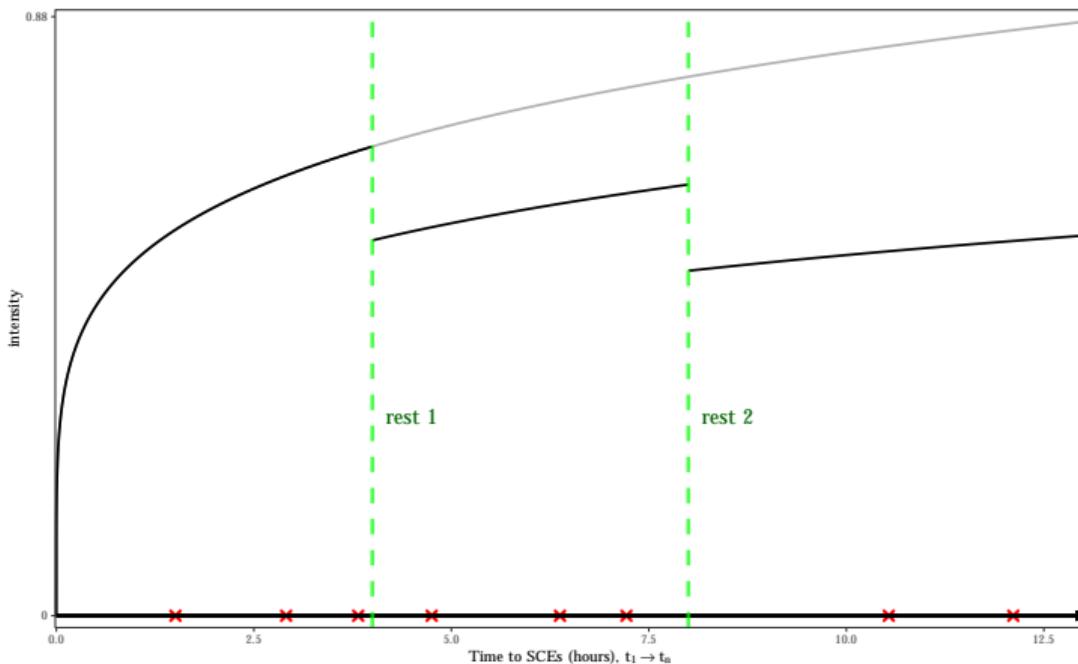

Figure 5: Intensity function, time to SCEs, and rest time within a shift with a jump-point PLP intensity function,  $\beta = 1.2$ ,  $\theta = 2$ ,  $\kappa = 0.8$

## Aim 3 - JPLP

JPLP: **an added parameter**  $\kappa$  based on Bayesian hierarchical PLP.

$$T_{d,s,1}, T_{d,s,2}, \dots, T_{d,s,n_{d,s}} \sim \text{JPLP}(\beta, \theta_{d,s}, \kappa)$$

$$\beta \sim \text{Gamma}(1, 1)$$

$$\log \theta_{d,s} = \gamma_{0d} + \gamma_1 x_{d,s,1} + \gamma_2 x_{d,s,2} + \dots + \gamma_k x_{d,s,k}$$

$$\kappa \sim \text{Uniform}(0, 1)$$

$$\gamma_{01}, \gamma_{02}, \dots, \gamma_{0D} \sim \text{i.i.d. } N(\mu_0, \sigma_0^2)$$

$$\gamma_1, \gamma_2, \dots, \gamma_k \sim \text{i.i.d. } N(0, 10^2)$$

$$\mu_0 \sim N(0, 5^2)$$

$$\sigma_0 \sim \text{Gamma}(1, 1)$$

(7)

- $\beta$ : shape parameter that reflects the reliability changes of drivers,
- $\theta_{d,s}$ : a scale parameter,
- $\kappa$ : **the percent of intensity function recovery** once the driver takes a break.

## Aim 3 - potential problems and alternative plans

In the unlikely event that the JPLP fails to be models, I will use the **modulated PLP** proposed by Black and Rigdon (1996)<sup>29</sup>. The modulated PLP has well-defined data generating process, intensity function, and likelihood functions. If the JPLP does not work, I will revise the modulated PLP into **a hierarchical modulated PLP**.

The hierarchical JPLP and hierarchical modulated PLP will be estimated using Stan programs by adding self-defined likelihood function, which can be accessed via the `rstan` package in statistical computing environment R 3.6.0 on the OSC<sup>27,28,30</sup>.

## Conclusion and implications

- This work will illustrate the relationship between crashes and SCEs among truck drivers.
- The fusion of high-resolutional API and NDS data sets is an exciting opportunity.
- An R package NDS will be developed and help researchers to analyze large-scale NDS data sets.
- Self-written subsampling MCMC algorithms can be a useful solution for wide and long NDS datasets.
- The work will provide estimates of cumulative driving time on the risk of SCEs.
- The proposed JPLP will be an innovative reliability model for NDS datasets.
